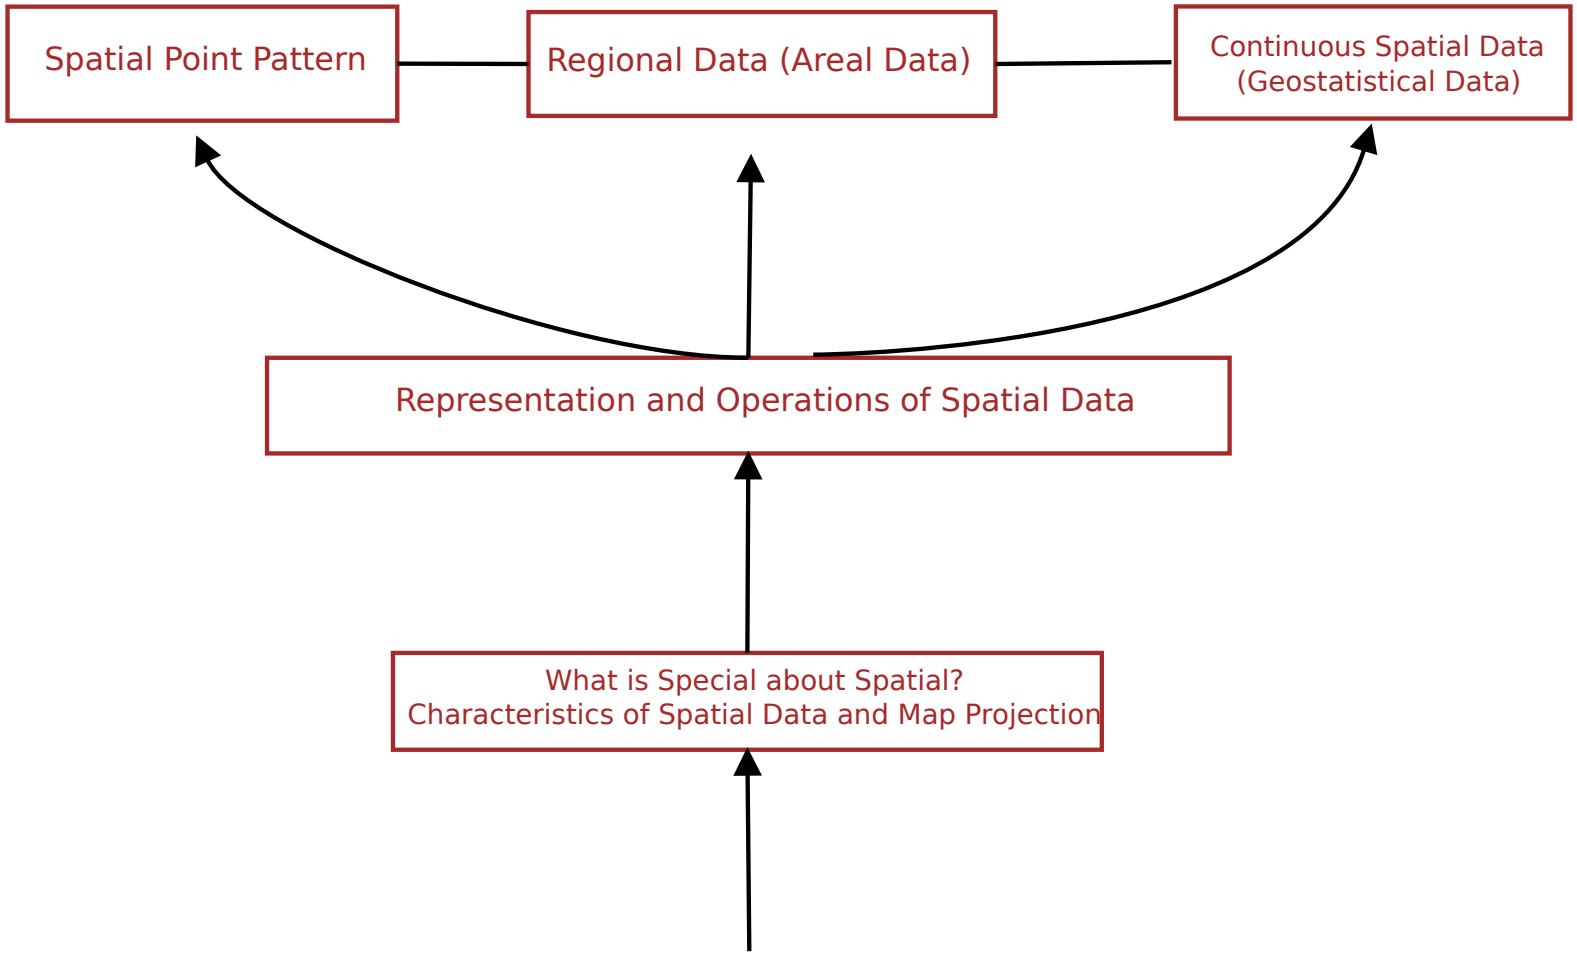
Spatial Analysis and Modeling (GIST 4302/5302)

Guofeng Cao
Department of Geosciences
Texas Tech University

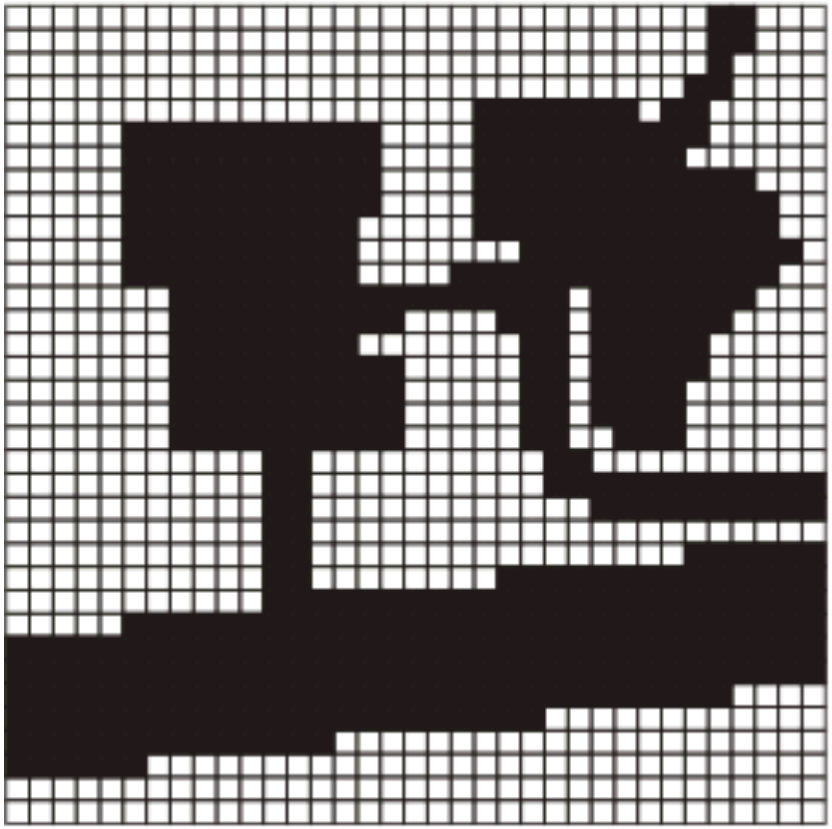
Class Outlines



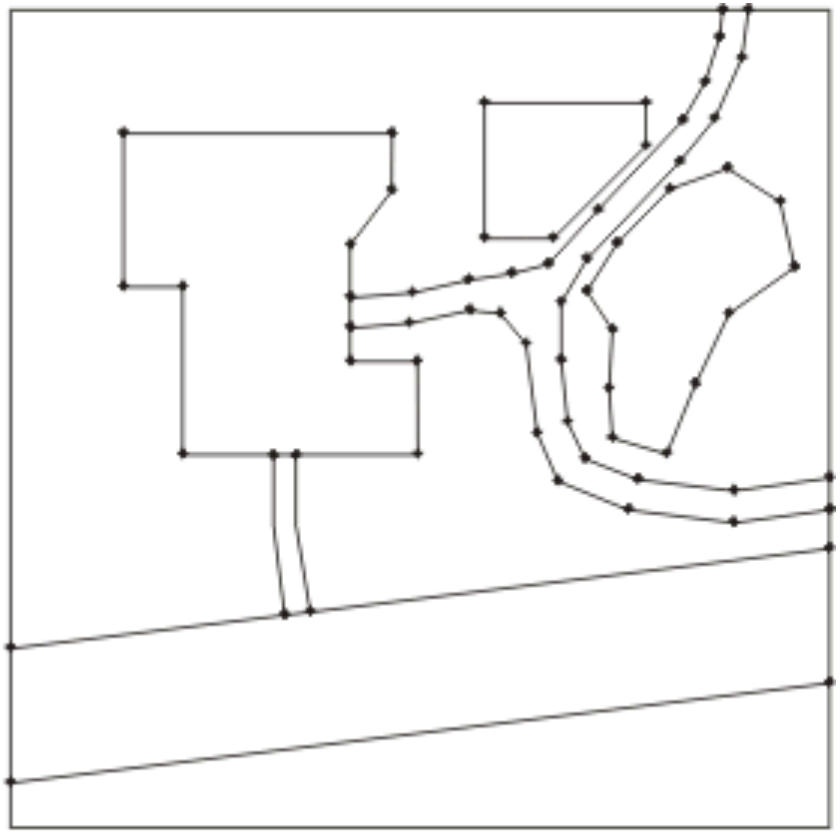
Representation of Spatial Data

Representation of Spatial Data Models

- ***Object-based model:*** treats the space as populated by discrete, identifiable entities each with a geospatial reference
  - Buildings or roads fit into this view
  - GIS Softwares: ArcGIS
- ***Field-based model:*** treats geographic information as collections of spatial distributions
  - Distribution may be formalized as a mathematical function from a spatial framework to an attribute domain
  - Patterns of topographic altitudes, rainfall, and temperature fit neatly into this view.
  - GIS Software: Grass



Raster



Vector

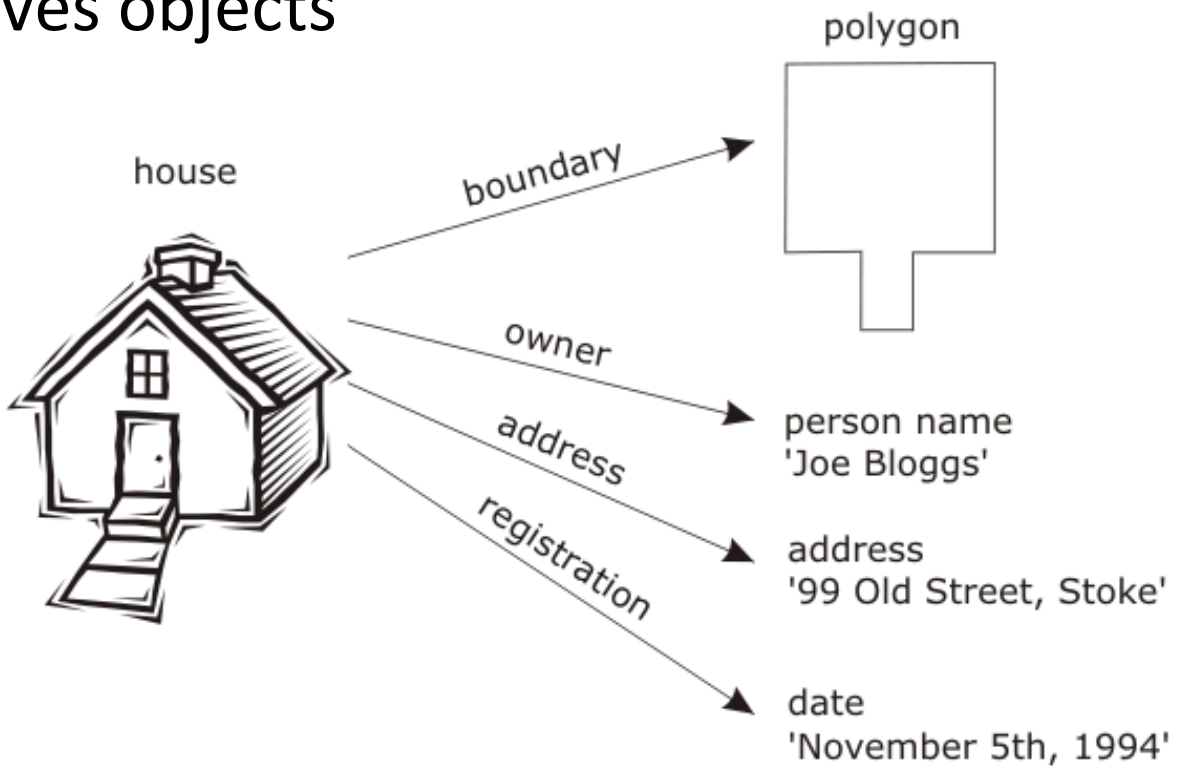
Object-based Approach

Entity

- Object-based models decompose an information space into objects or ***entities***
- An entity must be:
  - Identifiable
  - Relevant (be of interest)
  - Describable (have characteristics)
- The frame of spatial reference is provided by the entities themselves

Example: House object

Has several attributes, such as registration date, address, owner and boundary, which are themselves objects



Attribute Tables

3	Point	74	13	7.181452	70074	34.199444	-118.534722	-118.53472	34.19944

Attribute Tables

- Basic operators on attribute tables
  - Selection: picking certain rows
  - Projection: picking certain columns
  - Join: compositions of relations

Project Operator

- The **project** operator is unary
  - It outputs a new relation that has a subset of attributes
  - Identical tuples in the output relation are coalesced

Relation Sells:

bar	beer	price
Chimy's	Bud	2.50
Chimy's	Miller	2.75
Cricket's	Bud	2.50
Cricket's	Miller	3.00

Prices := $PROJ_{beer,price}$(Sells):

beer	price
Bud	2.50
Miller	2.75
Miller	3.00

Select Operator

- The **select** operator is unary
  - It outputs a new relation that has a subset of tuples
  - A condition specifies those tuples that are required

Relation Sells:

bar	beer	price
Chimy's	Bud	2.50
Chimy's	Miller	2.75
Cricket's	Bud	2.50
Cricket's	Miller	3.00

ChimyMenu := $\text{SELECT}_{\text{bar="Chimy's"}}$(Sells):

bar	beer	price
Chimy's	Bud	2.50
Chimy's	Miller	2.75

Join Operator

- The **join** operator is binary
  - It outputs the combined relation where tuples agree on a specified attribute (natural join)

Sells(bar,	beer,	price)
Chimy's	Bud	2.50
Chimy's	Miller	2.75
Cricket's	Bud	2.50
Cricket's	Coors	3.00

Bars(bar,	address)
Chimy's	2417 Broadway St.
Cricekt's	2412 Broadway St.

BarInfo := Sells JOIN Bars

Note Bars.name has become Bars.bar to make the natural join "work."

BarInfo(bar,	beer,	price,	address)
Chimy's	Bud	2.50	2417 Broadway St.
Chimy's	Milller	2.75	2417 Broadway St.
Cricket's	Bud	2.50	2412 Broadway St.
Cricket's	Coors	3.00	2412 Broadway St.

Join Operator

- Join is the most time-consuming of all relational operators to compute
  - In general, relational operators may not be arbitrarily reordered (left join, right join)
  - Query optimization aims to find an efficient way of processing queries, for example reordering to produce equivalent but more efficient queries

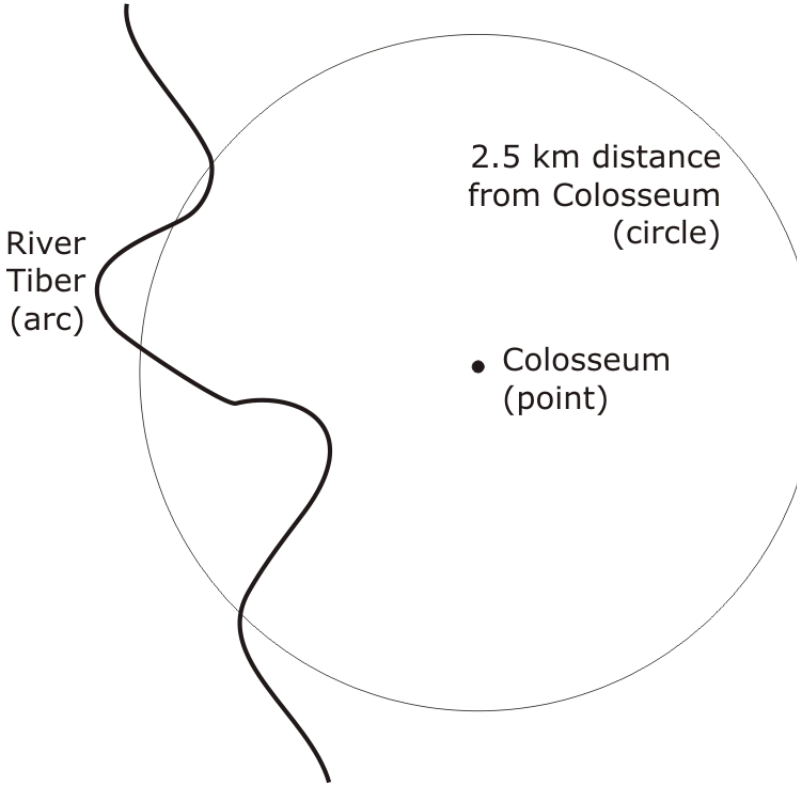
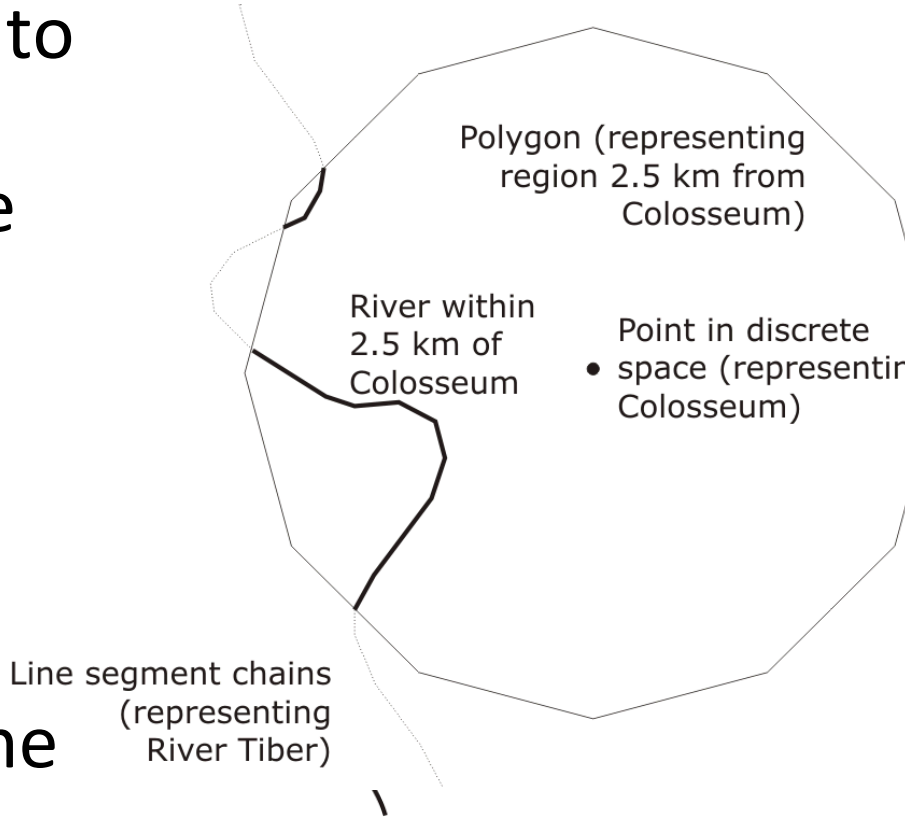
Example: GIS analysis

- For Italy's capital city, Rome, calculate the total length of the River Tiber which lies within 2.5 km of the Colosseum
  - First we need to model the relevant parts of Rome as objects
  - Operation ***length*** will act on ***arc***, and ***intersect*** will apply to form the piece of the ***arc*** in common with the disc



Example: GIS analysis

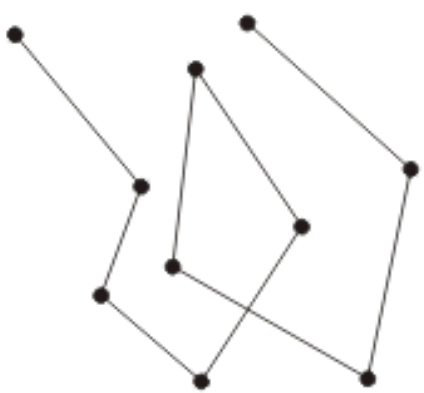
- A process of discretization must convert the objects to types that are computationally tractable
- A circle may be represented as a discrete polygonal area, arcs by chains of line segments, and points may be embedded in some discrete space



Primitive Objects

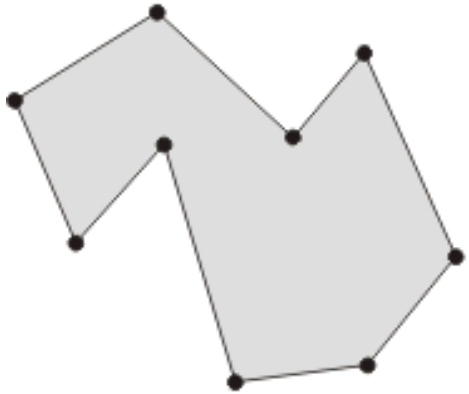
- ***Euclidean Space***: coordinatized model of space
  - Transforms spatial properties into properties of tuples of real numbers
  - Coordinate frame consists of a fixed, distinguished point (origin) and a pair of orthogonal lines (axes), intersecting in the origin
- Point objects
- Line objects
- Polygonal objects

Polygonal objects

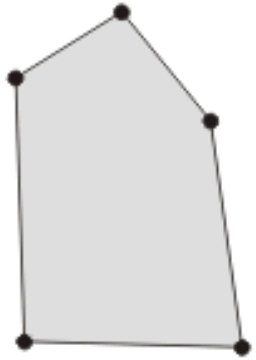


polyline

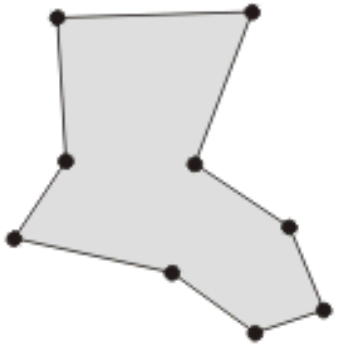
simple closed polyline



polygon

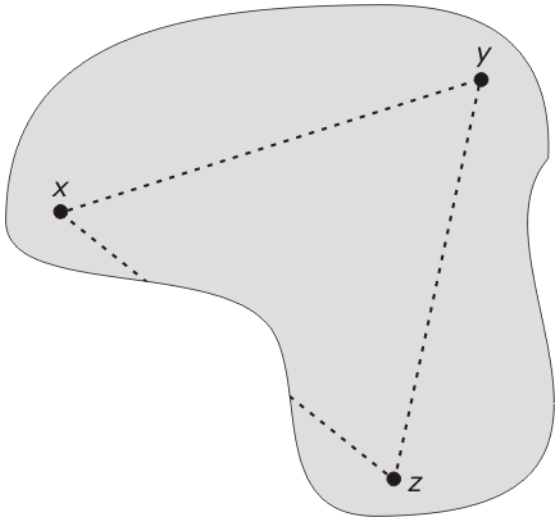


convex polygon

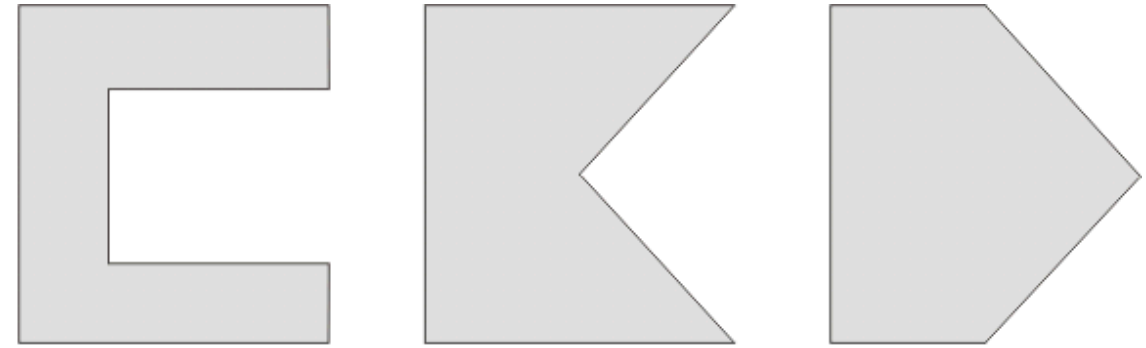


star-shaped polygon

Convexity



Visibility between points x, y, and z

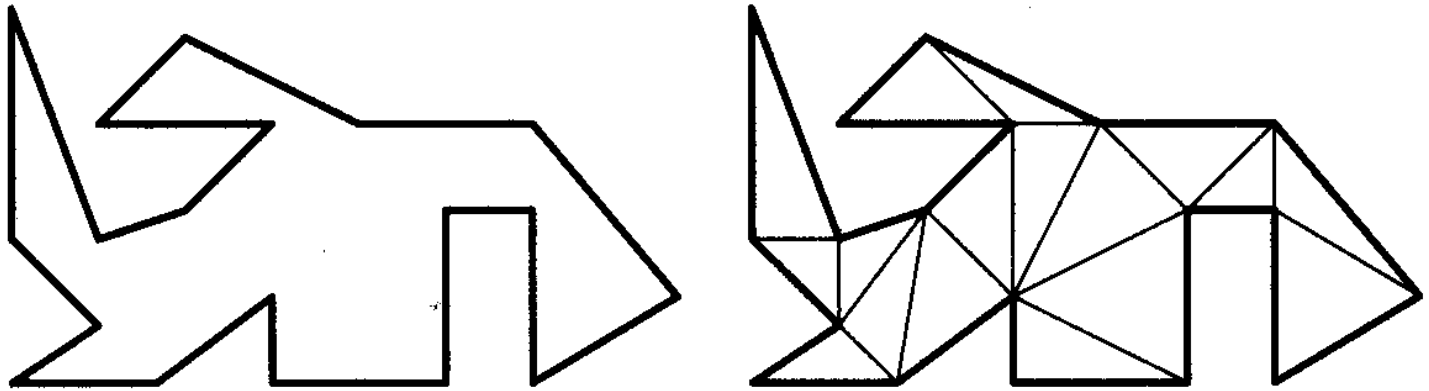


Not semi-convex

Semi-convex
Not convex

Convex

Example: Triangulation



- Every simple polygon has a triangulation. Any triangulation of a simple polygon with n vertices consists of exactly n – 2 triangles

- Art Gallery Problem
  - How many cameras are needed to guard a gallery and how should they be placed?
  - Upper bound N/3

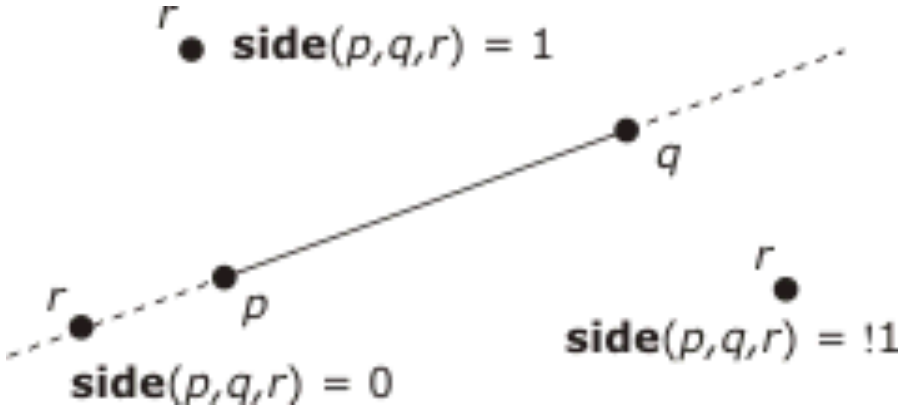
Primitive GIS Operations

- in Euclidean spaces
  - Length, bearing, area
    - How many ways you can think of to calculate the area of a polygon?
    - How to test which side of a point corresponding to a line?
  - Distance between objects (points, lines, polygons)
    - Distance could be ambiguous, e.g., what is the difference from Lubbock to Dallas (from city center or city boundary?).
  - Centroid
    - Not necessarily within in the boundary of polygon
  - Point in polygon
    - Ray casting method
  - Point on line
    - area
  - Buffer
  - Intersection/overlay
- In topological spaces
  - Spatial relations (within, touch, cover, …)

Area of a simple polygon

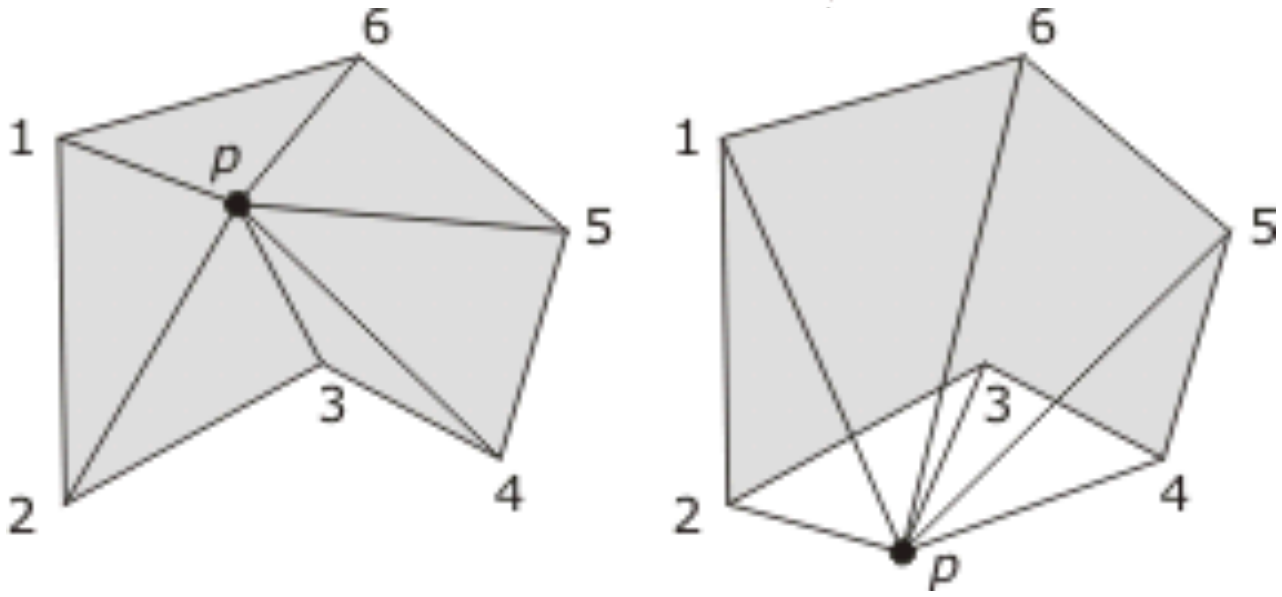
- Note that the area may be positive or negative
- In fact, **area**(*pqr*) = -**area**(*qpr*)
- If *p* is to the left of *qr* then the area is positive, if *p* is to the right of *qr* then the area is negative

$$\textbf{side}(p,q,r) = \begin{cases} 1 & \text{if } \textbf{area}(pqr) > 0 \quad (p \text{ is left of } qr) \\ 0 & \text{if } \textbf{area}(pqr) = 0 \quad (pqr \text{ are collinear}) \\ -1 & \text{if } \textbf{area}(pqr) < 0 \quad (p \text{ is right of } qr) \end{cases}$$



Point in polygon

- Determining whether a point is inside a polygon is one of the most fundamental operations in a spatial database
- ***Semi-line method (ray casting)*** : checks for odd or even numbers of intersections of a semi-line with polygon
- ***Winding method***: sums bearings from point to polygon vertices



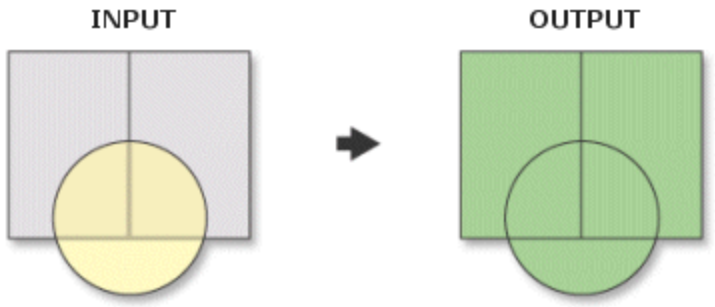
Is Biloxi in Mississippi?
1 intersection
= Hey Y'all!
1
Is New Orleans in Mississippi?
2 Intersections
= Reject-shon!
2
1

Primitive GIS operations: Overlay

- Union
- Intersect
- Erase
- Identity
- Update
- Spatial Join
- Symmetrical Difference

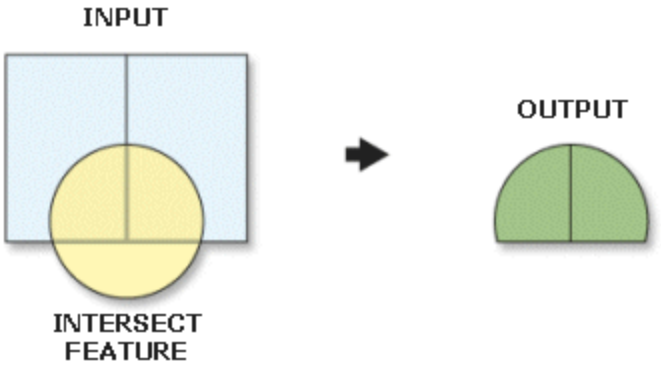
Overlay

- Union
  - Computes a geometric union of the input features. All features and their attributes will be written to the output feature class.



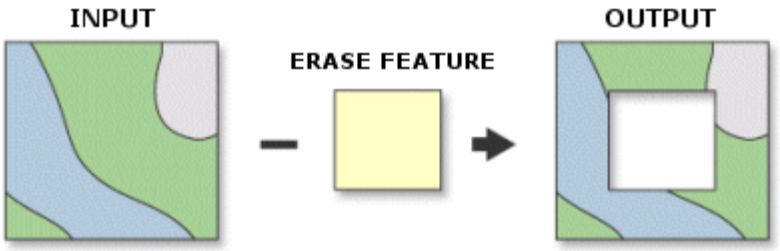
Overlay

- Intersect
  - Computes a geometric intersection of the input features. Features or portions of features which overlap in all layers and/or feature classes will be written to the output feature class.



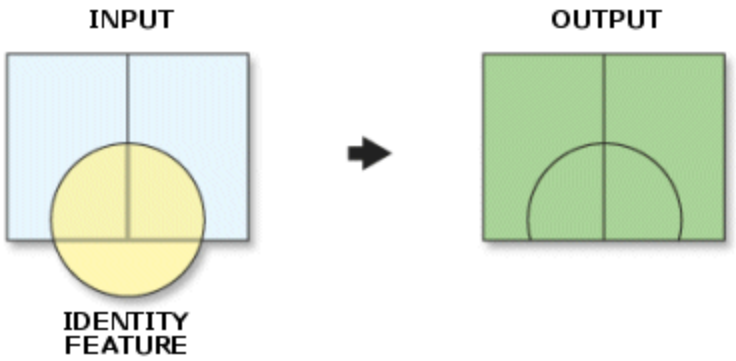
Overlay

- Erase
  - Creates a feature class by overlaying the Input Features with the polygons of the Erase Features. Only those portions of the input features falling outside the erase features outside boundaries are copied to the output feature class



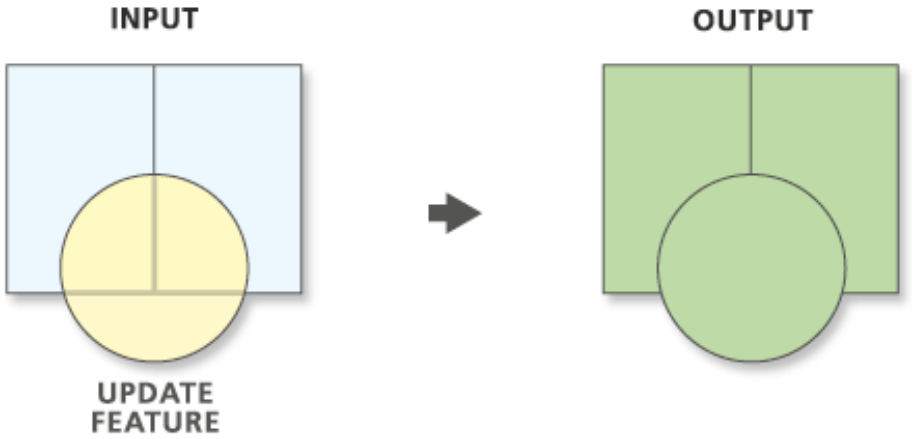
Overlay

- Identity
  - Computes a geometric intersection of the input features and identity features. The input features or portions thereof that overlap identity features will get the attributes of those identity features



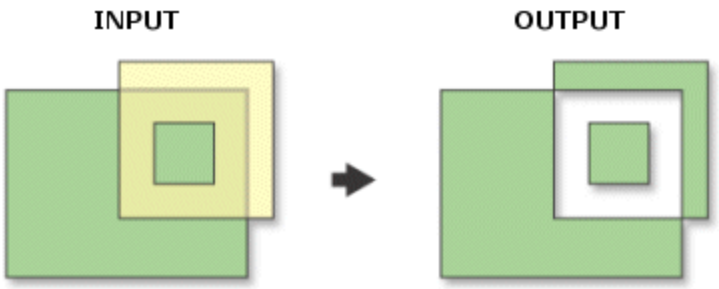
Overlay

- Update
  - Computes a geometric intersection of the Input Features and Update Features. The attributes and geometry of the input features are updated by the update features in the output feature class.



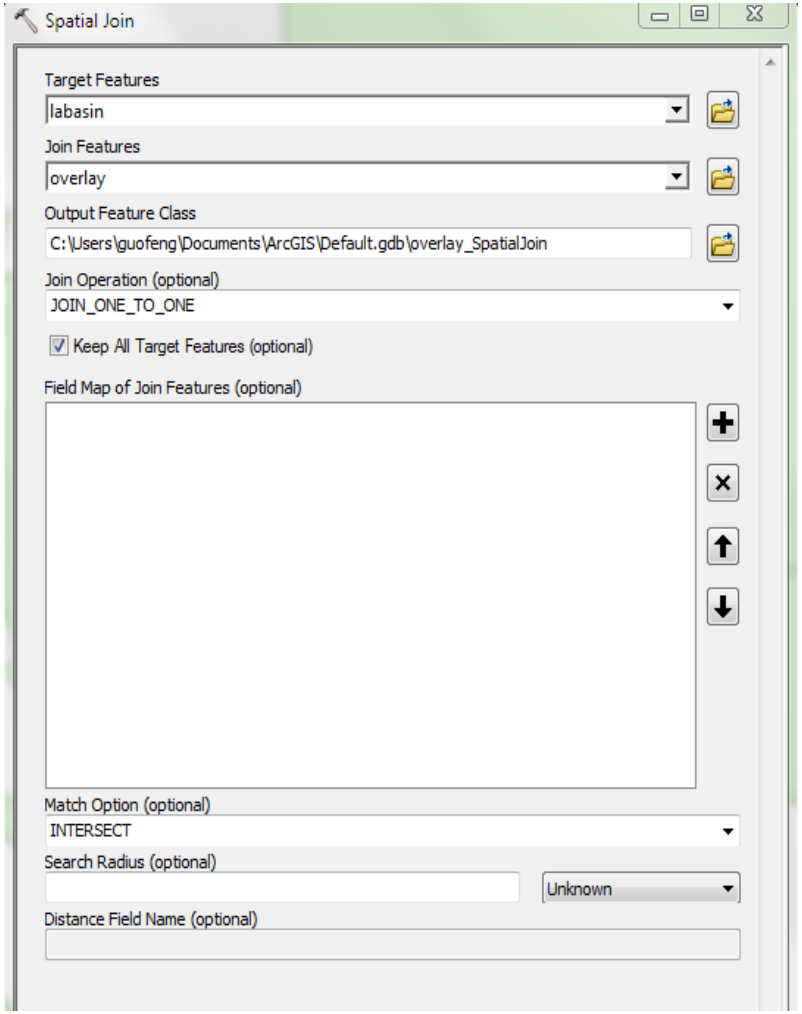
Overlay

- Symmetrical difference
  - Features or portions of features in the input and update features that do not overlap will be written to the output feature class.



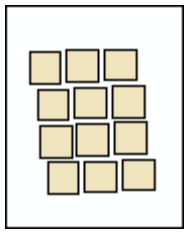
Overlay

- Spatial join
  - Joins attributes from one feature to another based on the spatial relationship. The target features and the joined attributes from the join features are written to the output feature class.

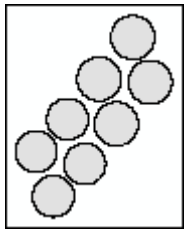


Quiz

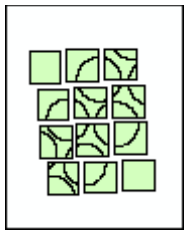
Input Feature



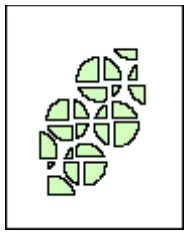
Overlay Feature



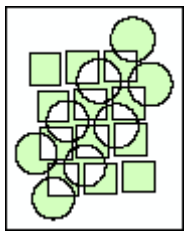
Which of the following is the result of identity, intersect, symmetrical difference, union and update respectively?



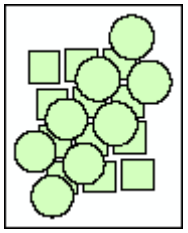
A



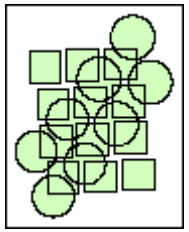
B



C

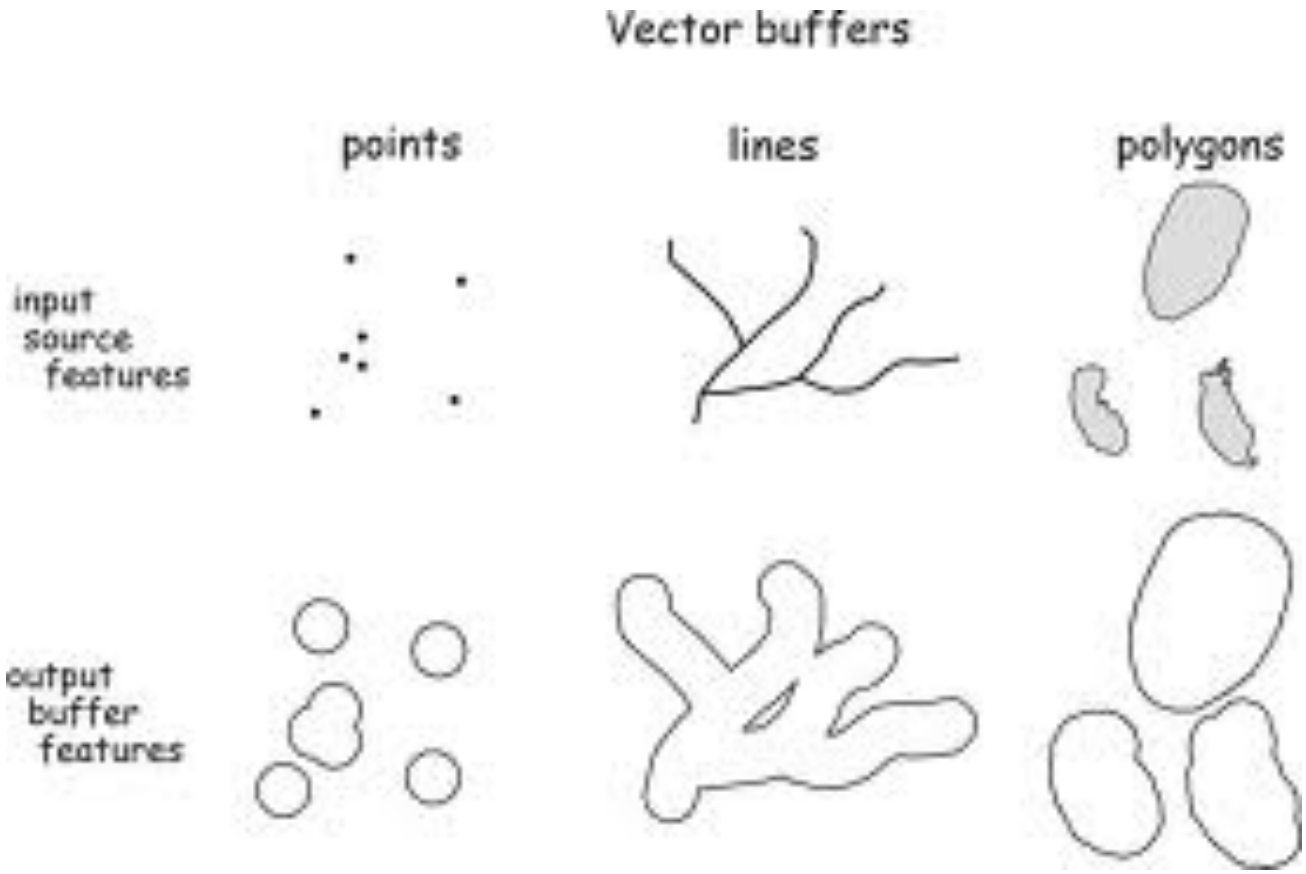


D



E

Buffer



Vector buffers
points
lines
polygons
input source features
output buffer features

- Primitive operators
  - you might already realized that these primitive operators are often used collaboratively with each other, and other analytical methods (e.g., dissolve, surface analysis, interpolation) that we will introduce in the coming lectures.

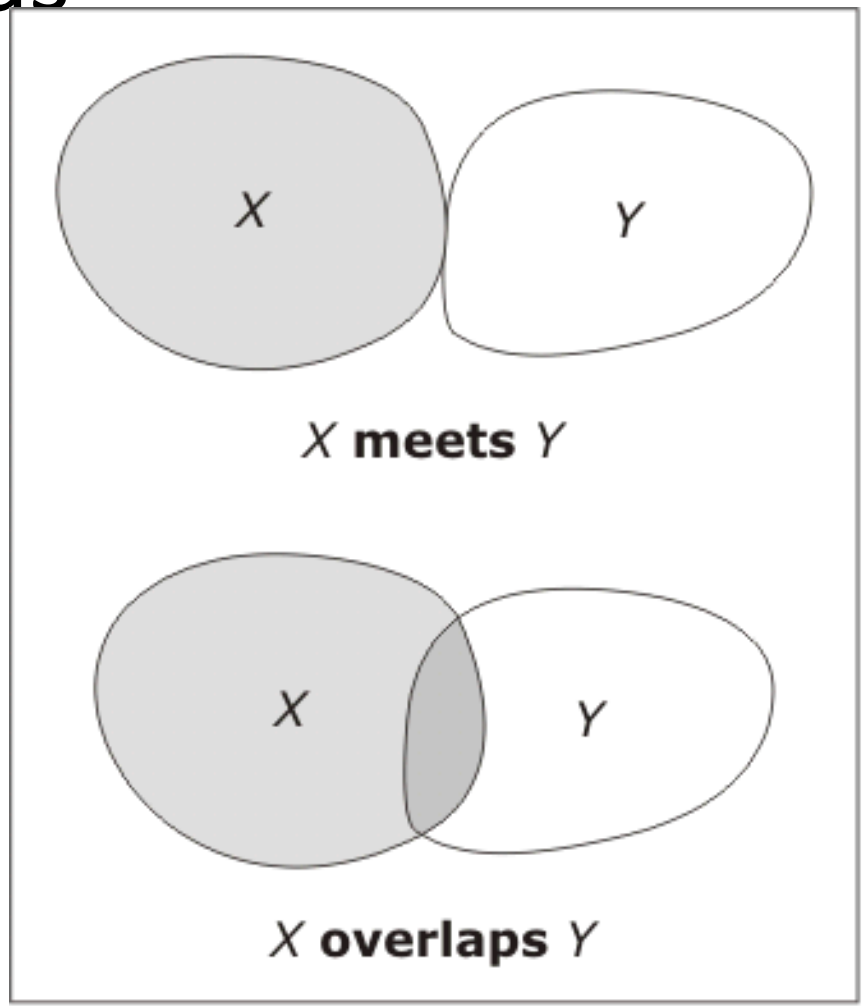
Topological spatial operations: spatial relationship

- Object types with an assumed underlying topology are ***point, arc***, ***loop*** and ***area***
- Operations:
  - ***boundary***, ***interior***, ***closure*** and ***connected*** are defined in the usual manner
  - ***components*** returns the set of maximal connected components of an area
  - ***extremes*** acts on each object of type arc and returns the pair of points of the arc that constitute its end points
  - ***is within*** provides a relationship between a point and a simple loop, returning true if the point is enclosed by the loop

Topological spatial operations for areas

- *X* ***meets*** *Y* if *X* and *Y* touch externally in a common portion of their boundaries

- *X* ***overlaps*** *Y* if *X* and *Y* impinge into each other's interiors

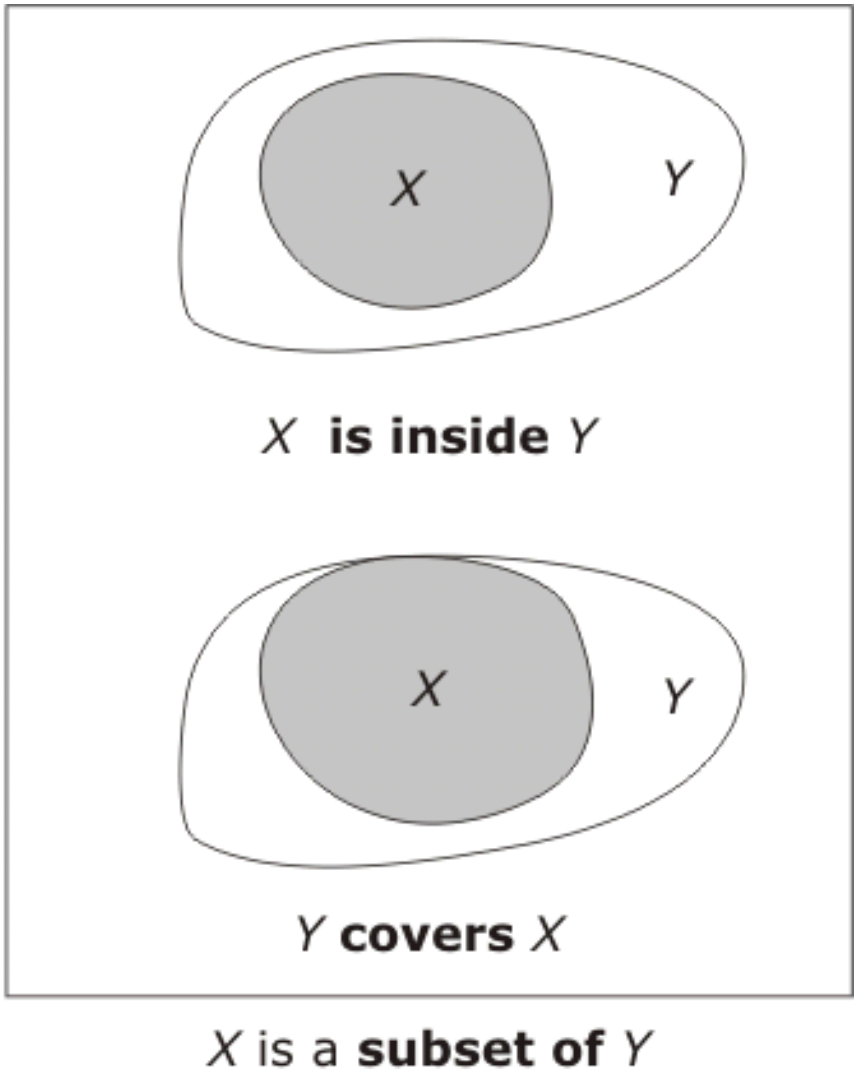


X is not **disjoint from** *Y*

Topological spatial operations for areas

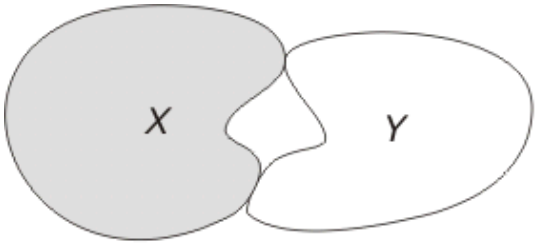
- *X* ***is inside*** *Y* if *X* is a subset of *Y* and *X*, *Y* do not share a common portion of boundary

- *X* ***covers*** *Y* if *Y* is a subset of *X* and *X*, *Y* touch externally in a common portion of their boundaries

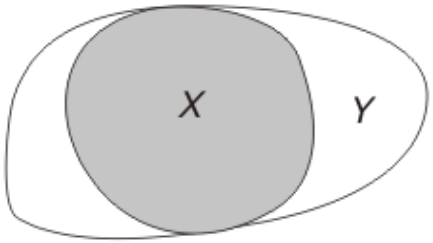


Topological spatial operations

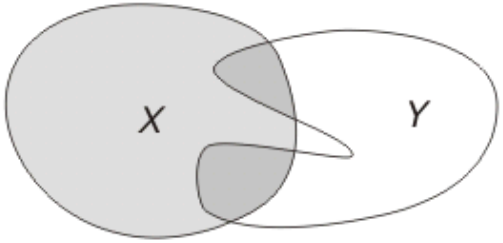
- There are an infinite number of possible topological relationships that are available between objects of type cell



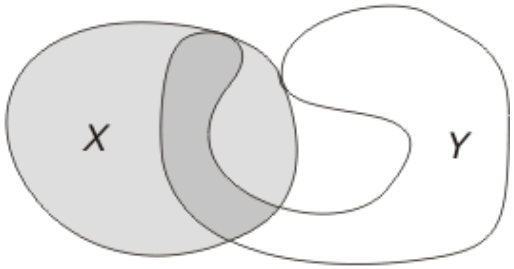
X **2-meets** *Y*

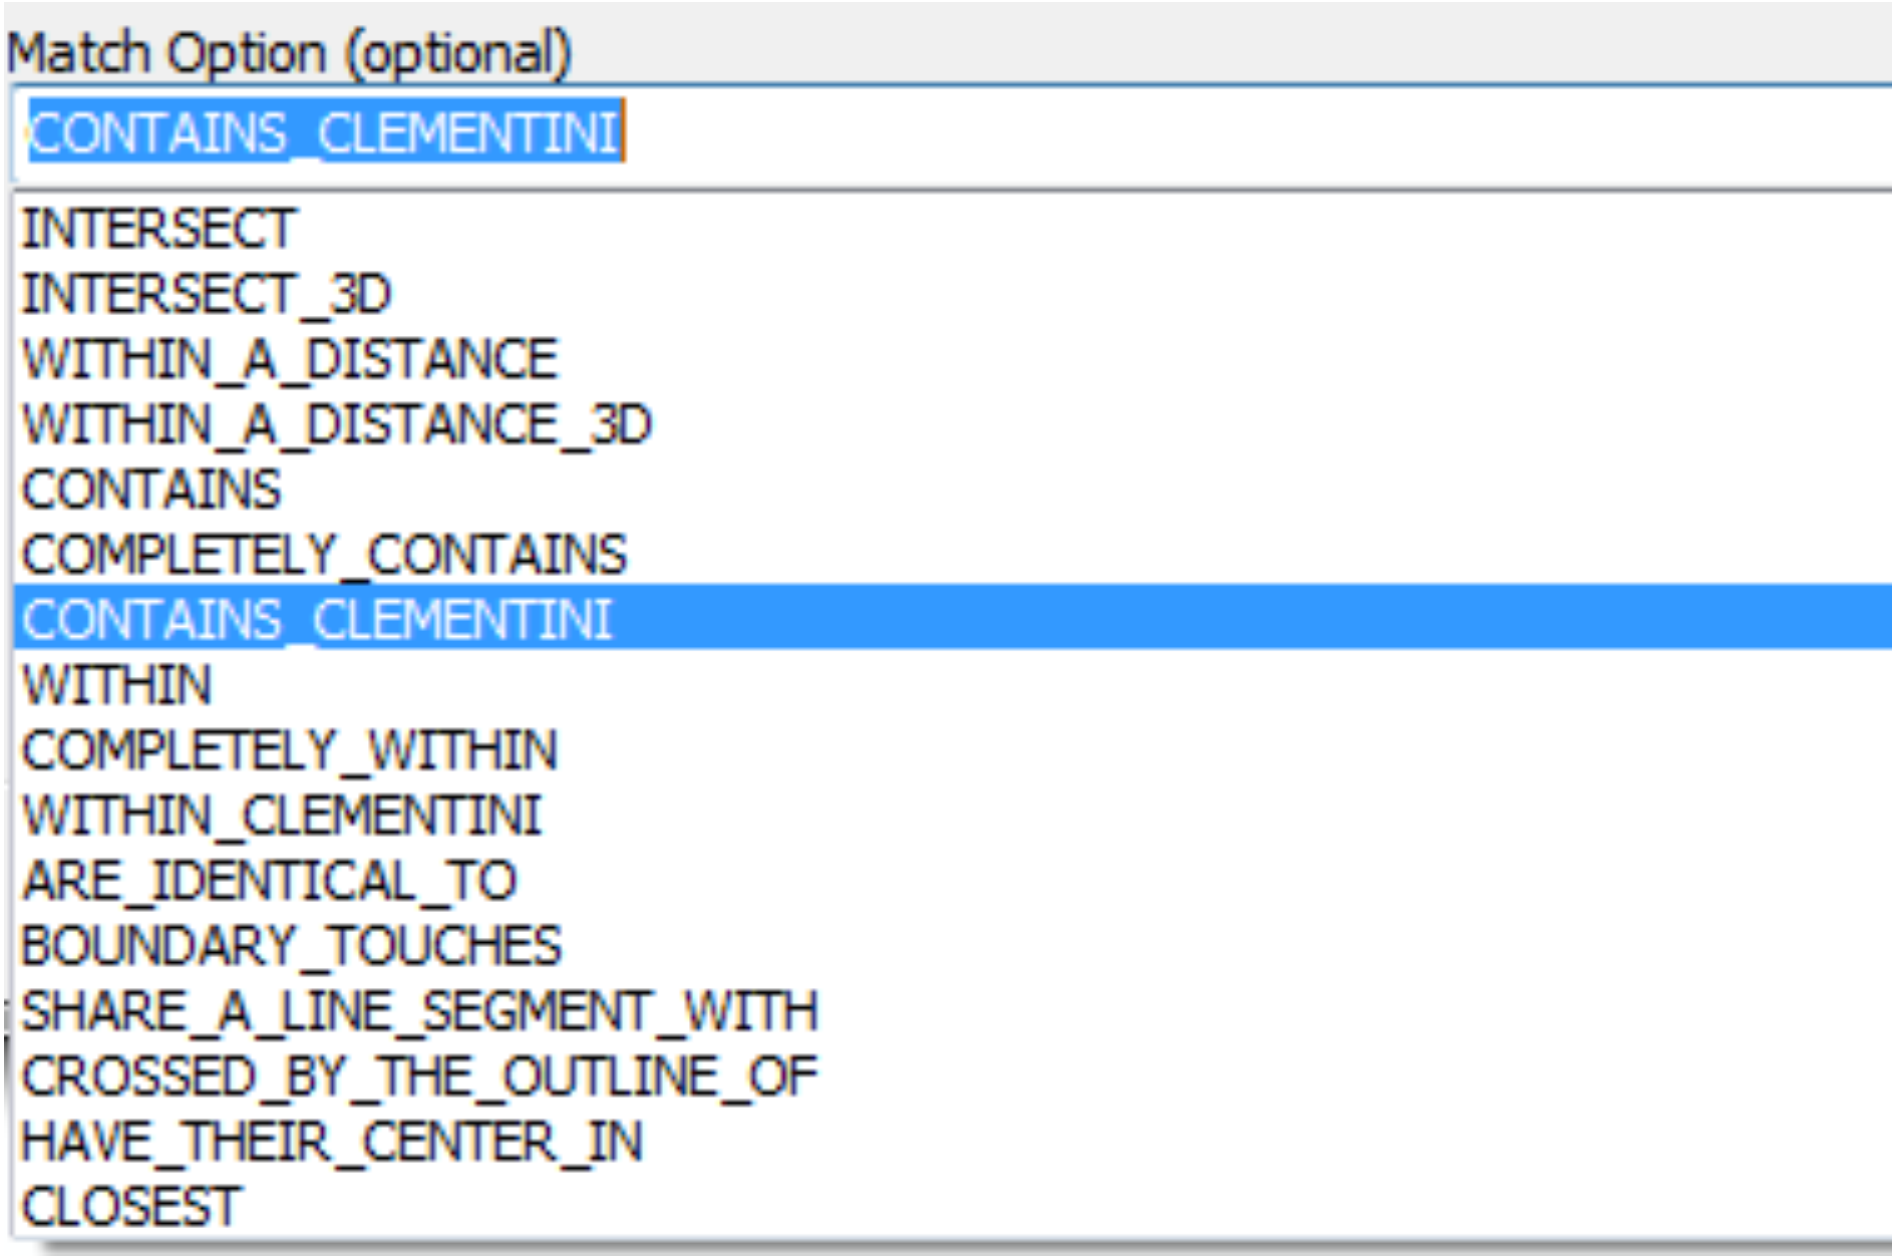


Y **2-covers** *X*



X **2-overlaps** *Y*



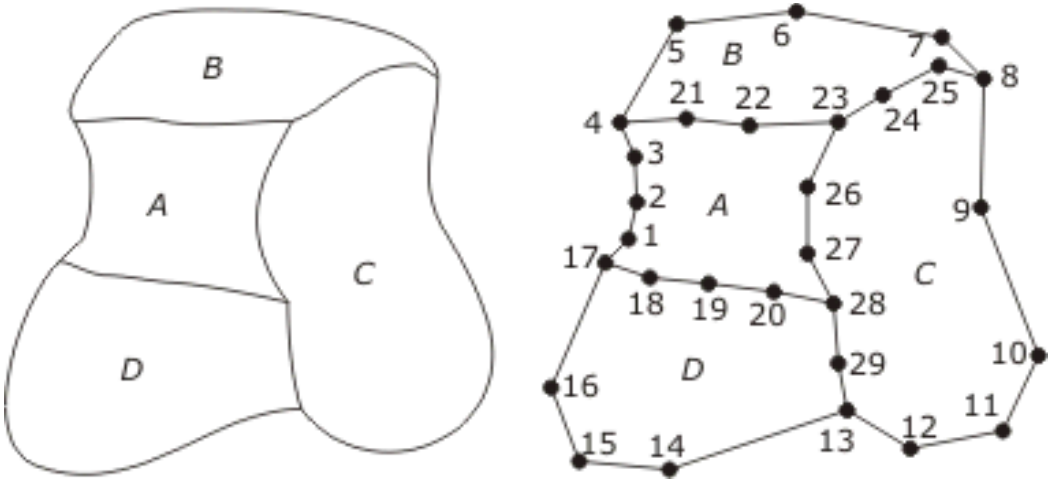


http://resources.esri.com/help/9.3/ArcGISDesktop/com/Gp_ToolRef/Data_Management_toolbox/select_by_location_colon_graphical_examples.htm

- Contain vs CONTAINS_CLEMENTINI:
  - the results of CONTAINS_CLEMENTINI will be identical to CONTAINS with the exception that if the feature in the Selecting Features layer is entirely on the boundary of the Input Feature Layer, with no part of the contained feature properly inside the feature in the Input Feature Layer, the input feature will not be selected.

Spaghetti

- ***Spaghetti*** data structure represents a planar configuration of points, arcs, and areas
- Geometry is represented as a set of lists of straight-line segments



Spaghetti- example

- Each polygonal area is represented by its boundary loop
- Each loop is discretized as a closed polyline
- Each polyline is represented as a list of points

A:[1,2,3,4,21,22,23,26,27,28,20,19,18,17]

B:[4,5,6,7,8,25,24,23,22,21]

C:[8,9,10,11,12,13,29,28,27,26,23,24,25]

D:[17,18,19,20,28,29,13,14,15,16]

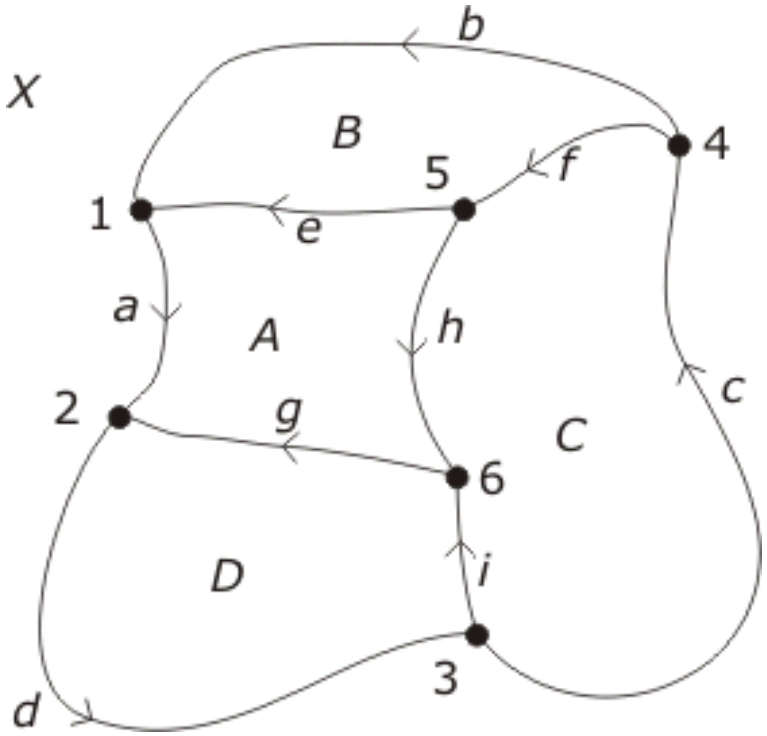
Issues

- There is **NO** explicit representation of the topological interrelationships of the configuration, such as adjacency
- Data consistence issues
  - *Silver polygons*
  - *Data redundancy*

NAA: node arc area

- Each directed arc has exactly one start and one end node.
- Each node must be the start node or end node (maybe both) of at least one directed arc.
- Each area is bounded by one or more directed arcs.
- Directed arcs may intersect only at their end nodes.
- Each directed arc has exactly one area on its right and one area on its left.
- Each area must be the left area or right area (maybe both) of at least one directed arc.

NAA: planar decomposition



Arc	Begin	End	Left	Right
a	1	2	*A*	*X*
b	4	1	*B*	*X*
c	3	4	*C*	*X*
d	2	3	*D*	*X*
e	5	1	*A*	*B*
f	4	5	*C*	*B*
g	6	2	*D*	*A*
h	5	6	*C*	*A*
i	3	6	*D*	*C*

Field-based Approach

Seminar Announcement

Title: Global Observation Without Clouds in Only 5 Days

Speaker: Bo Zhong (Institute of Remote Sensing and Digital Earth, Chinese Academy of Science)

When and Where: Today 3pm at

Experimental Science Building 120

Spatial fields

- If the spatial framework is a Euclidean plane and the attribute domain is a subset of the set of real numbers;
  - The Euclidean plane plays the role of the horizontal xy-plane
  - The ***spatial field*** values give the z-coordinates, or "heights" above the plane

Regional Climate Variations

Imagine placing a square grid over a region and measuring aspects of the climate at each node of the grid. Different fields would then associate locations with values from each of the measured attribute domains.

Properties of the attribute domain

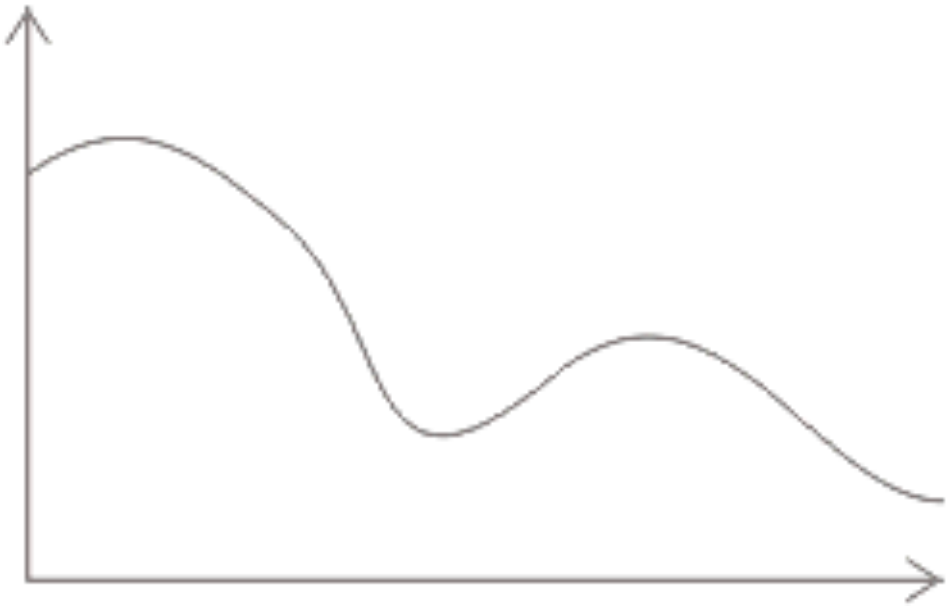
- The attribute domain may contain values which are commonly classified into four levels of measurement
  - ***Nominal attribute***: simple labels; qualitative; cannot be ordered; and arithmetic operators are not permissible
  - ***Ordinal attribute***: ordered labels; qualitative; and cannot be subjected to arithmetic operators, apart from ordering
  - ***Interval attributes***: quantities on a scale without any fixed point; can be compared for size, with the magnitude of the difference being meaningful; the ratio of two interval attributes values is not meaningful
  - ***Ratio attributes***: quantities on a scale with respect to a fixed point; can support a wide range of arithmetical operations, including addition, subtraction, multiplication, and division

Continuous and differentiable fields

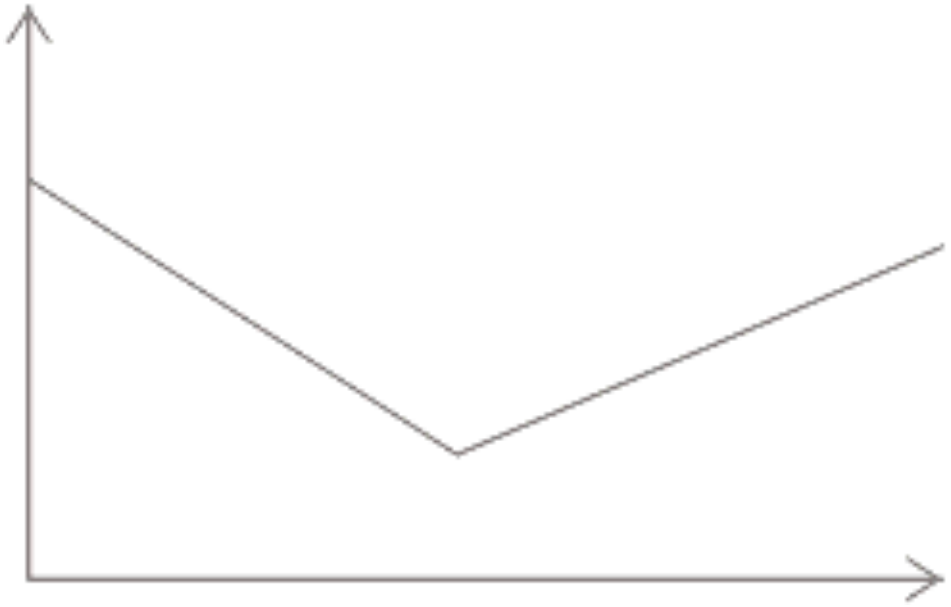
- ***Continuous*** field: small changes in location leads to small changes in the corresponding attribute value
- ***Differentiable*** field: rate of change (slope) is defined everywhere
- Spatial framework and attribute domain must be continuous for both these types of fields
- Every differentiable field must also be continuous, but not every continuous field is differentiable

One dimensional examples

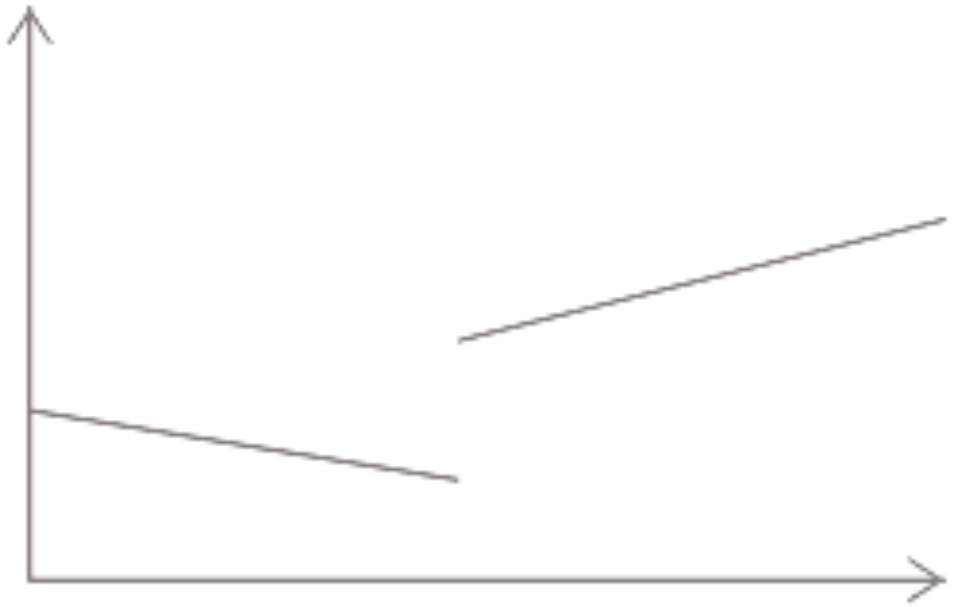
- Fields may be plotted as a graph of attribute value against spatial framework



One dimensional examples

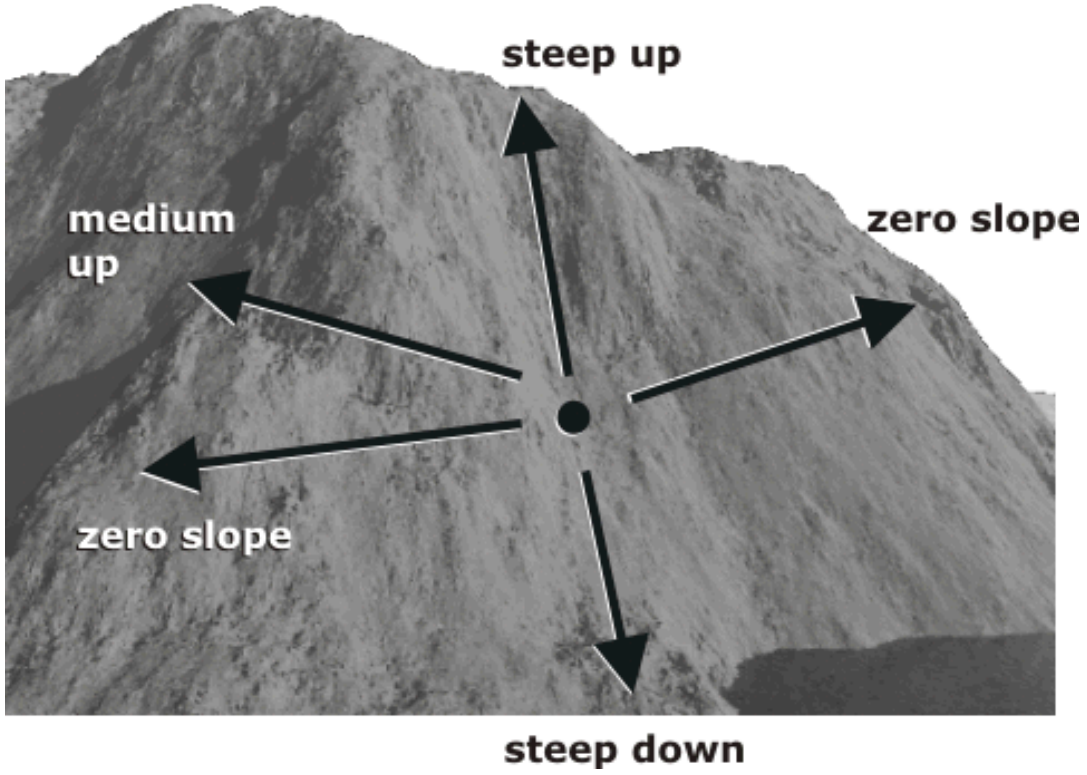


One dimensional examples



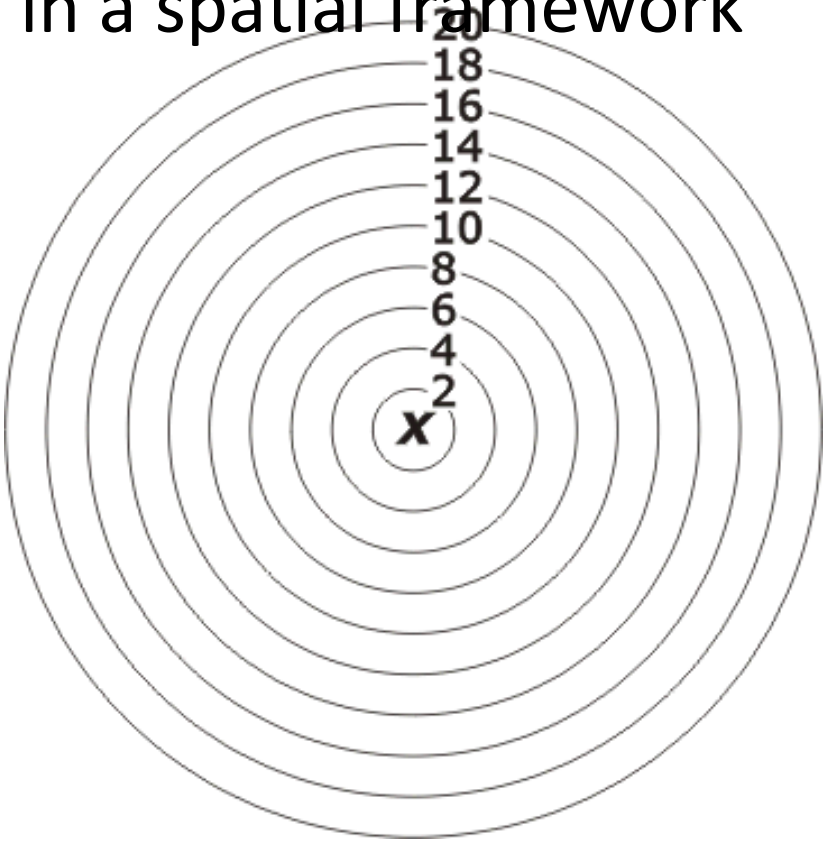
Two dimensional examples

- The slope is dependent on the particular location and on the bearing at that location



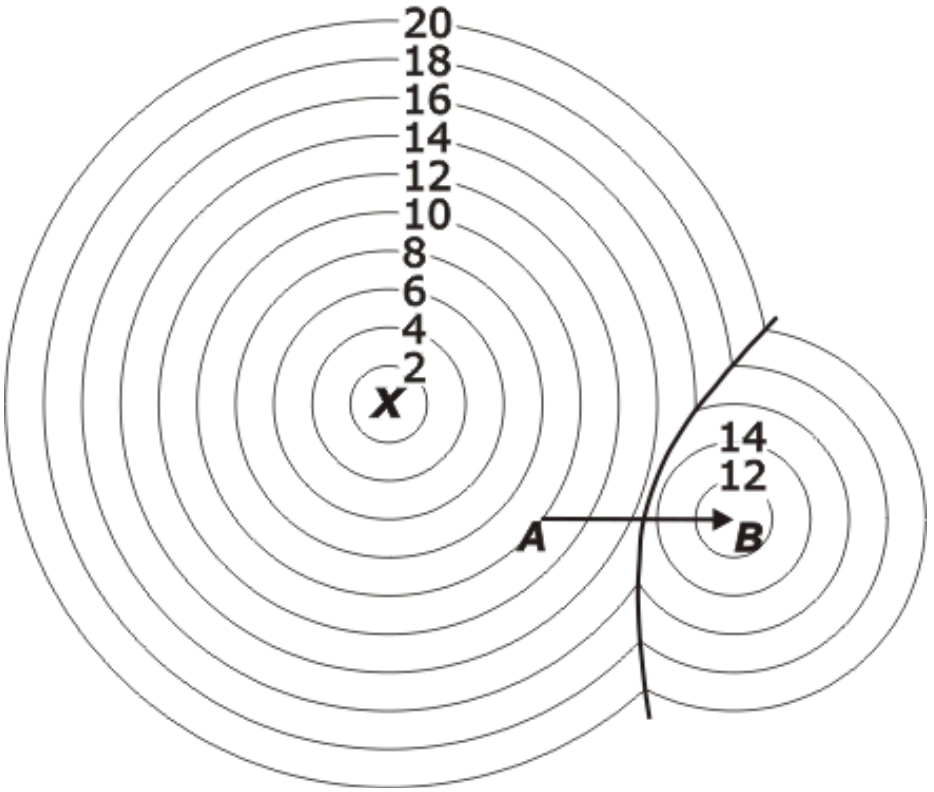
Isotropic fields

- A field whose properties are independent of direction is called an ***isotropic field***
- Consider travel time in a spatial framework
  - The time from X to any point Y is dependent only upon the distance between X and Y and independent of the bearing of Y from X



Anisotropic fields

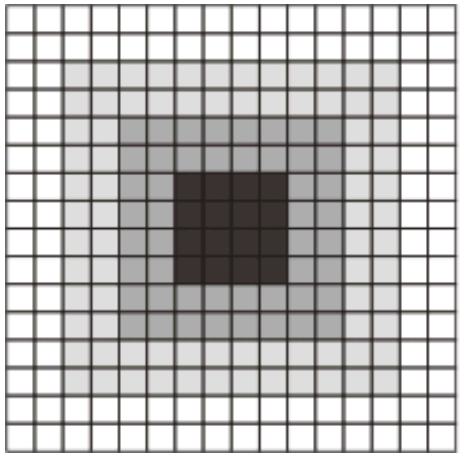
- A field whose properties are dependent on direction is called an ***anisotropic field***.
- Suppose there is a high speed link *AB*
  - For points near *B* it would be better, if traveling from *X,* to travel to *A*, take the link, and continue on from *B* to the destination
  - ***The direction to the destination is important***

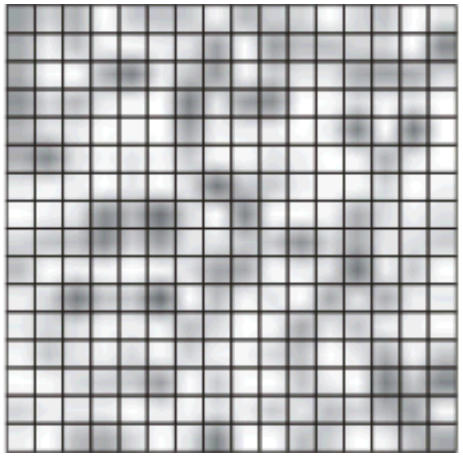


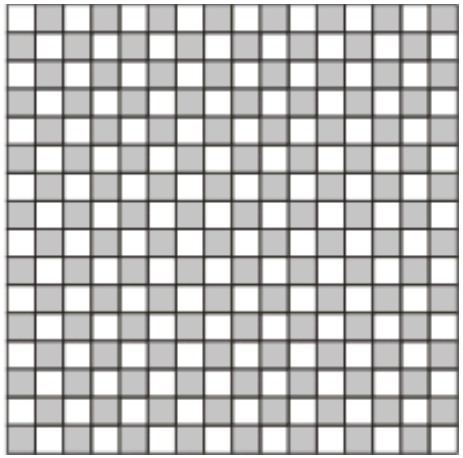
Spatial autocorrelation

- Spatial autocorrelation is a quantitative expression of Tobler's first law of geography (1970)
  - "Everything is related to everything else, but near things are more related than distant thing"
  - Spatial autocorrelation measures the degree of clustering of values in a spatial field
- Also termed as spatial dependency, spatial pattern, spatial context, spatial similarity, spatial dissimilarity…

Autocorrelation







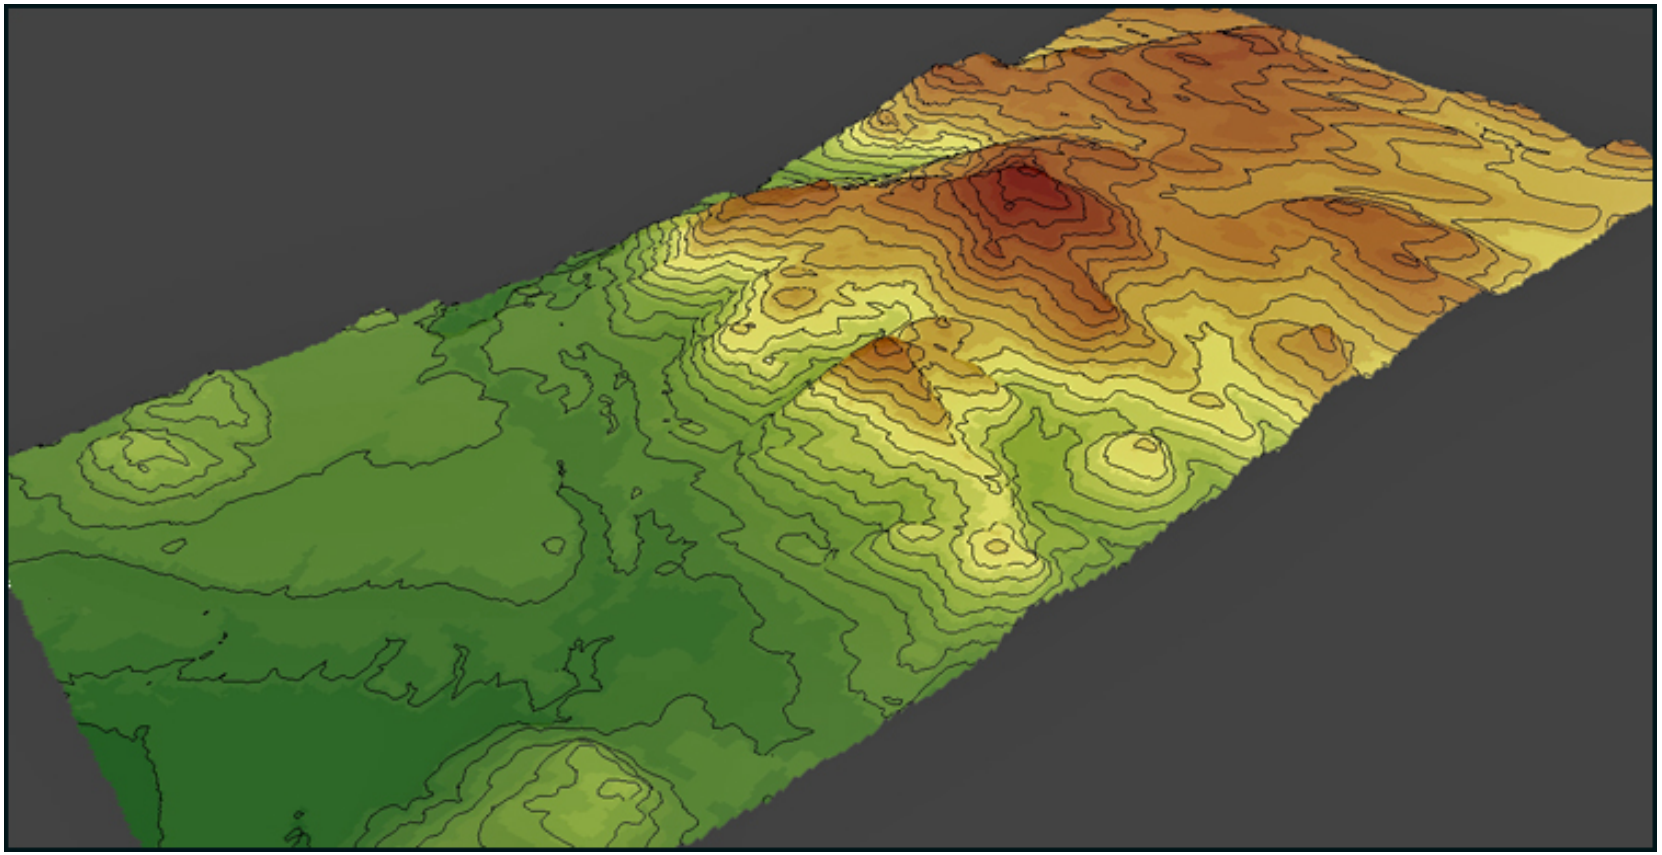
If there is no apparent relationship between attribute value and location then there is **zero spatial autocorrelation**

Representations of Spatial Fields

- Points
- Contours
- Raster/Lattice
- Triangulation (Delaunay Trangulation)

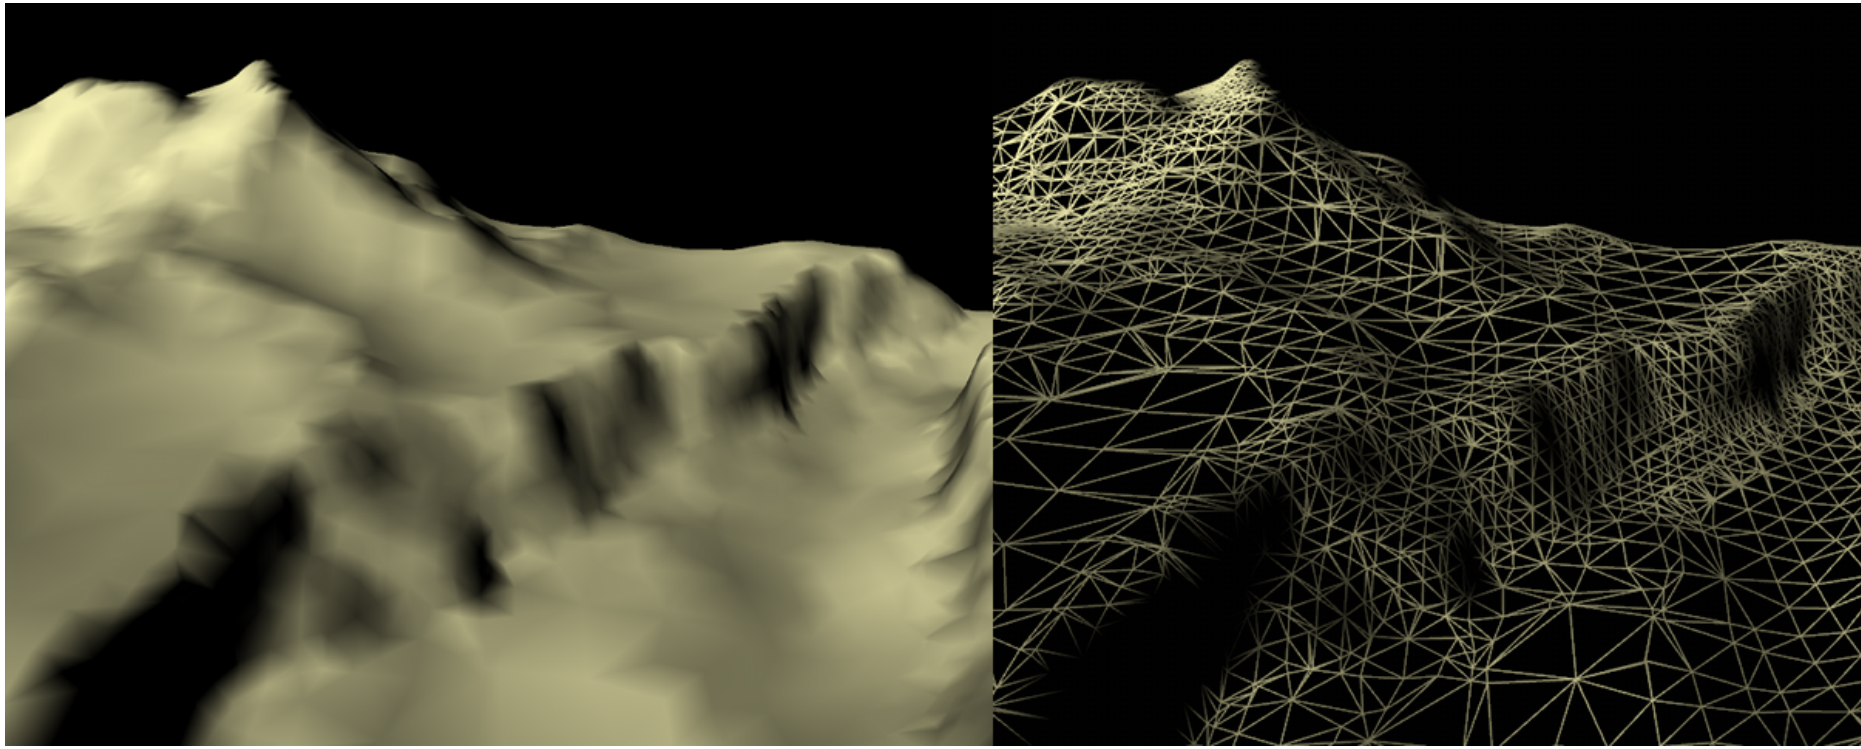
Example

- Contour lines and raster



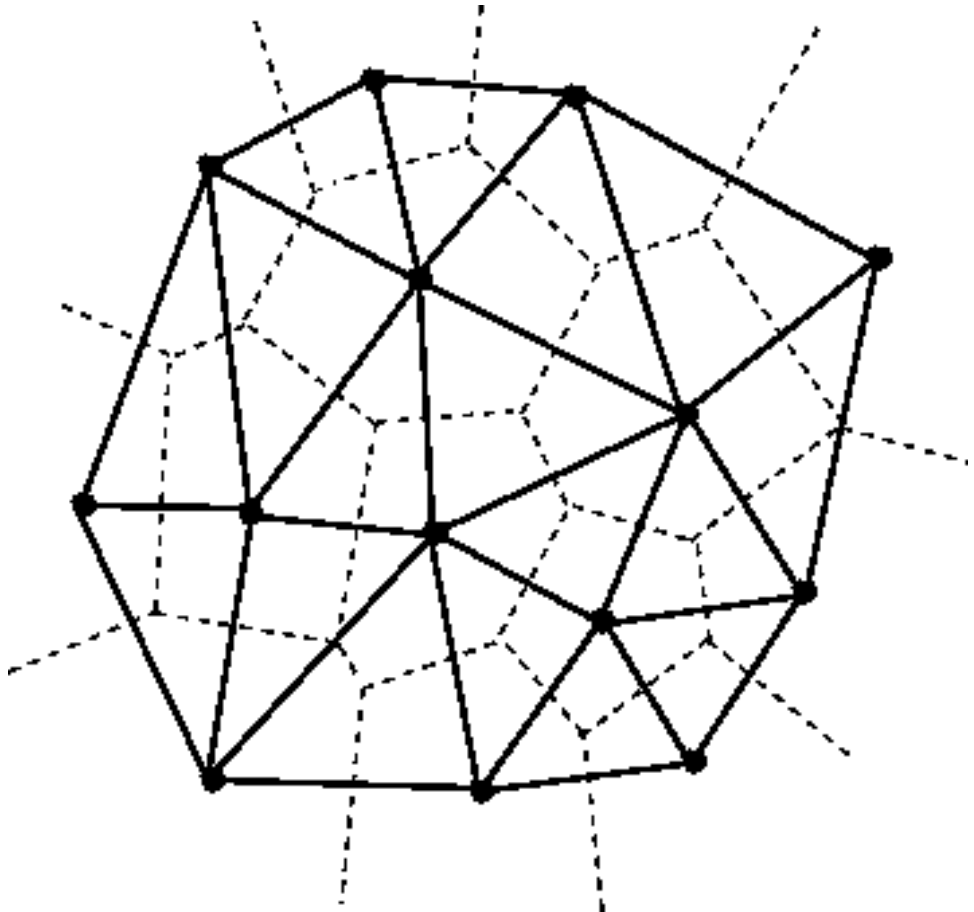
Example

- Trangulations



Side Note: Delaunay Triangulation and Voronoi Diagram

- Dual Graph

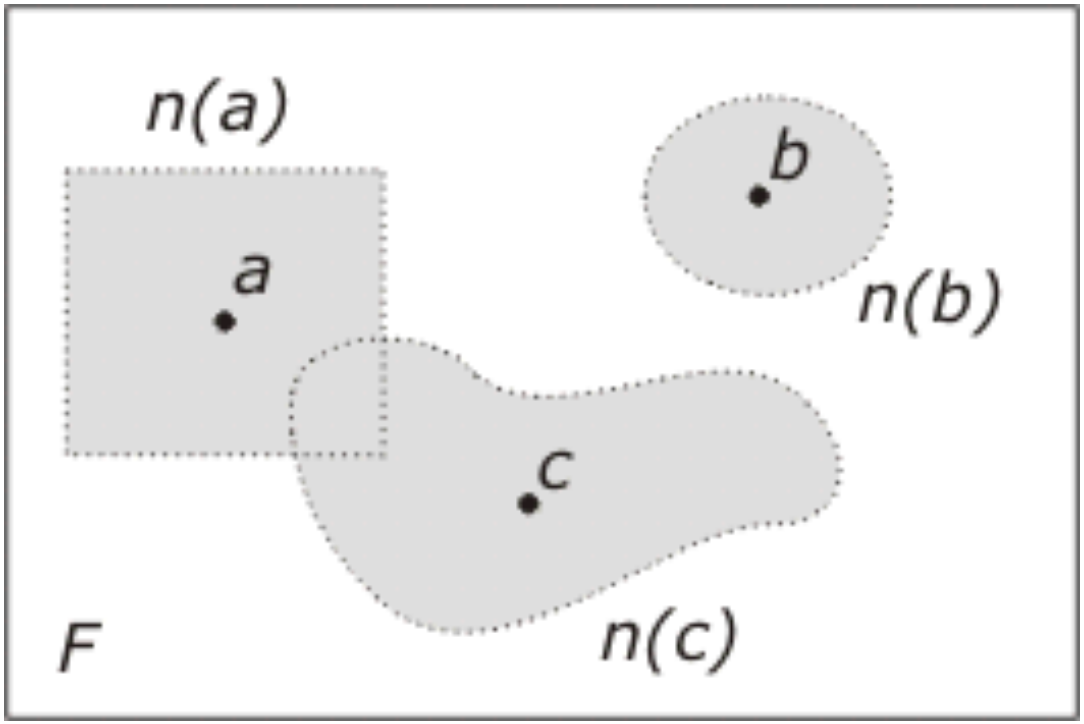


Operations on fields

- A field operation takes as input one or more fields and returns a resultant field
- The system of possible operations on fields in a field-based model is referred to as ***map algebra***
- Three main classes of operations
  - Local
  - Focal
  - Zonal

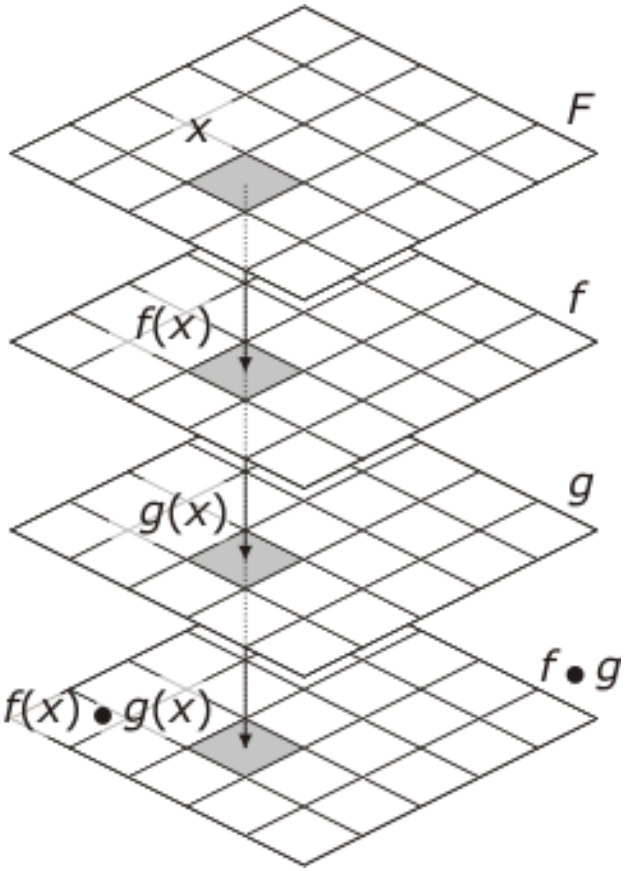
Neighborhood function

- Given a spatial framework *F*, a ***neighborhood function*** *n* is a function that associates with each location *x* a set of locations that are "near" to *x*



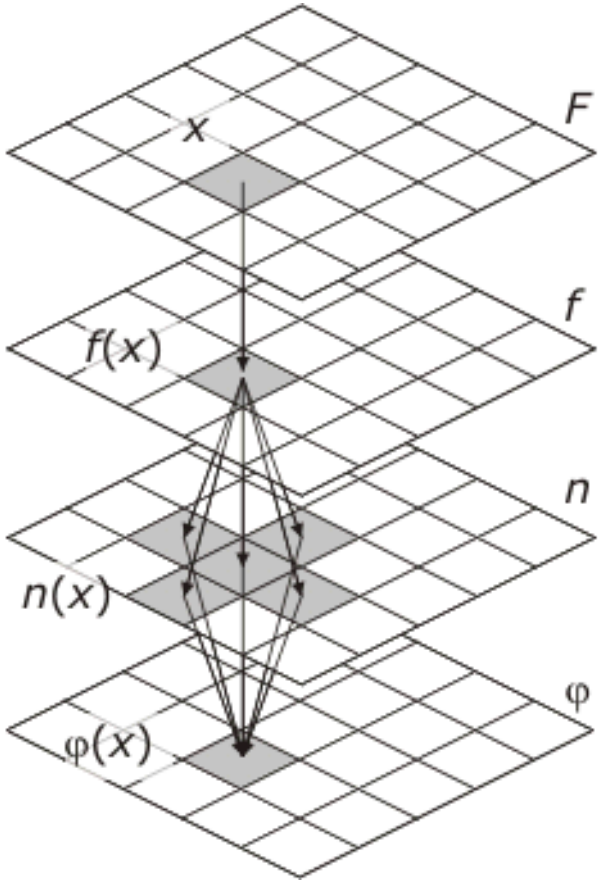
Local operations

- ***Local operation:*** acts upon one or more spatial fields to produce a new field
- The value of the new field at any location is dependent on the values of the input field function at that location
  - is any binary operation



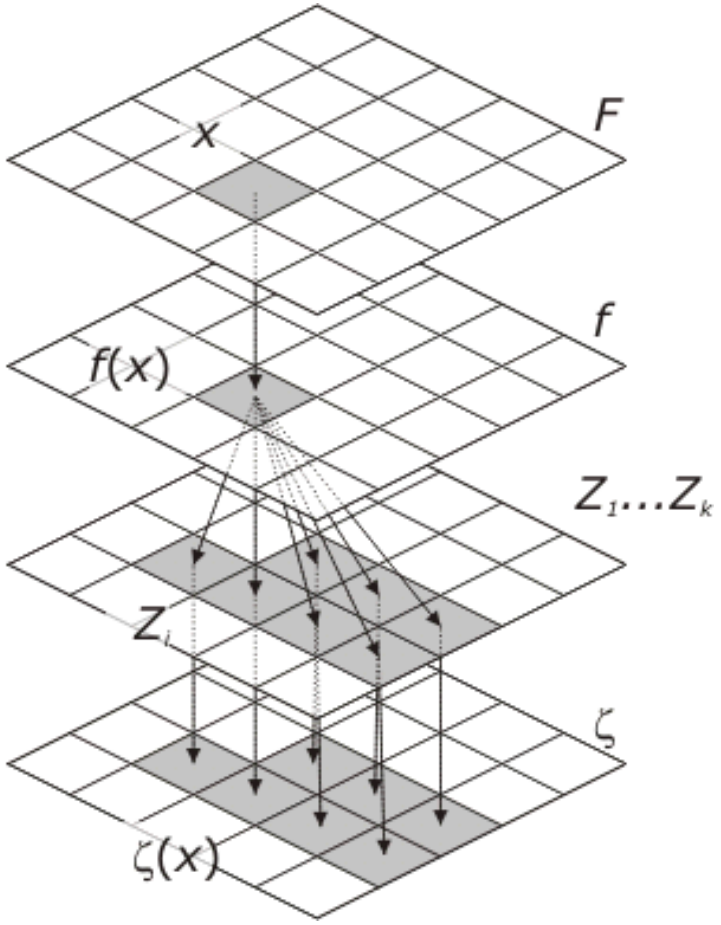
Focal operations

- ***Focal operation***: the attribute value derived at a location *x* may depend on the attributes of the input spatial field functions at *x* and the attributes of these functions in the neighborhood *n*(*x*) of *x*



Zonal operations

- ***Zonal operation***: aggregates values of a field over a set of zones (arising in general from another field function) in the spatial framework
- For each location *x*:
  1. Find the Zone Z_i in which *x* is contained
  2. Compute the values of the field function *f* applied to each point in Z_i
  3. Derive a single value $\zeta(x)$ of the new field from the values computed in step 2



Summary: Object-based vs Field-based models

- Object-based models:
  - Greater precision
  - Less redundant information (smaller storage footprints)
  - Complex data structures
- Field-based models:
  - Simpler data structures
  - More redundant information (larger storage footprints)
  - Less precision
- *Raster is faster, but vector is corrector*

Raster <-> Vector

- Vector-> Raster
  - Interpolation
    - Inverse distance weighted, Kriging, Spline
  - Density surface
    - Kernel density
  - Rasterization
- Raster->Vector
  - Watershed
  - Vectorization (raster to polygon)
  - …

Model Builder

- Graphic Programming
- Reusable operations
- Streamline the workflow
